## **ABSTRACT**

This is one of a series of annual basic-data reports that have been prepared by the U.S. Geological Survey since 1970 presenting results of systematic measurements in principal estuaries along the Texas coast. Approximately 170 designated data-collection sites were visited during the 1976 water year. The report contains field measurements of dissolved oxygen, specific conductance, temperature, pH, transparency, and turbidity at several points along a vertical at each site. Also listed are the results of laboratory analyses of samples from selected sites, including the principal inorganic ions, biochemical oxygen demand, phenols, organic carbon, insecticides and herbicides, ammonium, nitrite, nitrate, phosphate, and other selected ions such as aluminum, arsenic, cadmium, chromium, cobalt, copper, iron, lead, lithium, manganese, mercury, nickel, strontium, and zinc. Water and sediment sampling is represented. Objectives of the continuing investigation are to define: the occurrence, source, and distribution of nutrients; the physical, organic, and inorganic water-quality constituents and their areal distribution and time variations; the chemical and physical characteristics of gulf water that enters the estuaries; the occurrence, quality, quantity, and dispersion of drainage entering the estuarine systems; and the current patterns, directions, and rates of water movement.

**CHEMICAL AND PHYSICAL CHARACTERISTICS OF  
WATER IN ESTUARIES OF TEXAS  
OCTOBER 1975—SEPTEMBER 1976**

By

William B. Lind  
U.S. Geological Survey

**INTRODUCTION**

**Purpose and Scope of the Investigation**

The Texas Water Plan (Texas Water Development Board, 1968) proposes development and utilization of water resources in Texas and includes provision for the use and preservation of water in the estuaries of the State. Management of estuarine waters requires knowledge of the hydrodynamics and of the continuing changes in the chemical and physical characteristics of water in the estuaries.

In September 1967, the U.S. Geological Survey and the Texas Water Development Board (now Texas Department of Water Resources) began a cooperative water-resources investigation of the principal estuaries along the Texas coast (Figure 1) except the Rio Grande estuary, which is under the jurisdiction of the International Boundary and Water Commission, United States and Mexico.

The objectives of the investigation are to define: (1) the occurrence, source, and distribution of nutrients; (2) the physical, organic, and inorganic water-quality constituents and their areal distribution and time variations; (3) the chemical and physical characteristics of gulf water that enters the estuaries; (4) the occurrence, quality, quantity, and dispersion of drainage entering the estuarine systems; and (5) the current patterns, directions, and rates of water movement.

The coastal waters of Texas are not classical estuaries, but are similar to them in ecosystems and mixing phenomena. A description of various types of estuaries is presented in "Estuaries," edited by Lauff (1967, p. 3-11). The term estuary, as used in this report, refers to concomitant water bodies in which streamflow mixes with seawater.

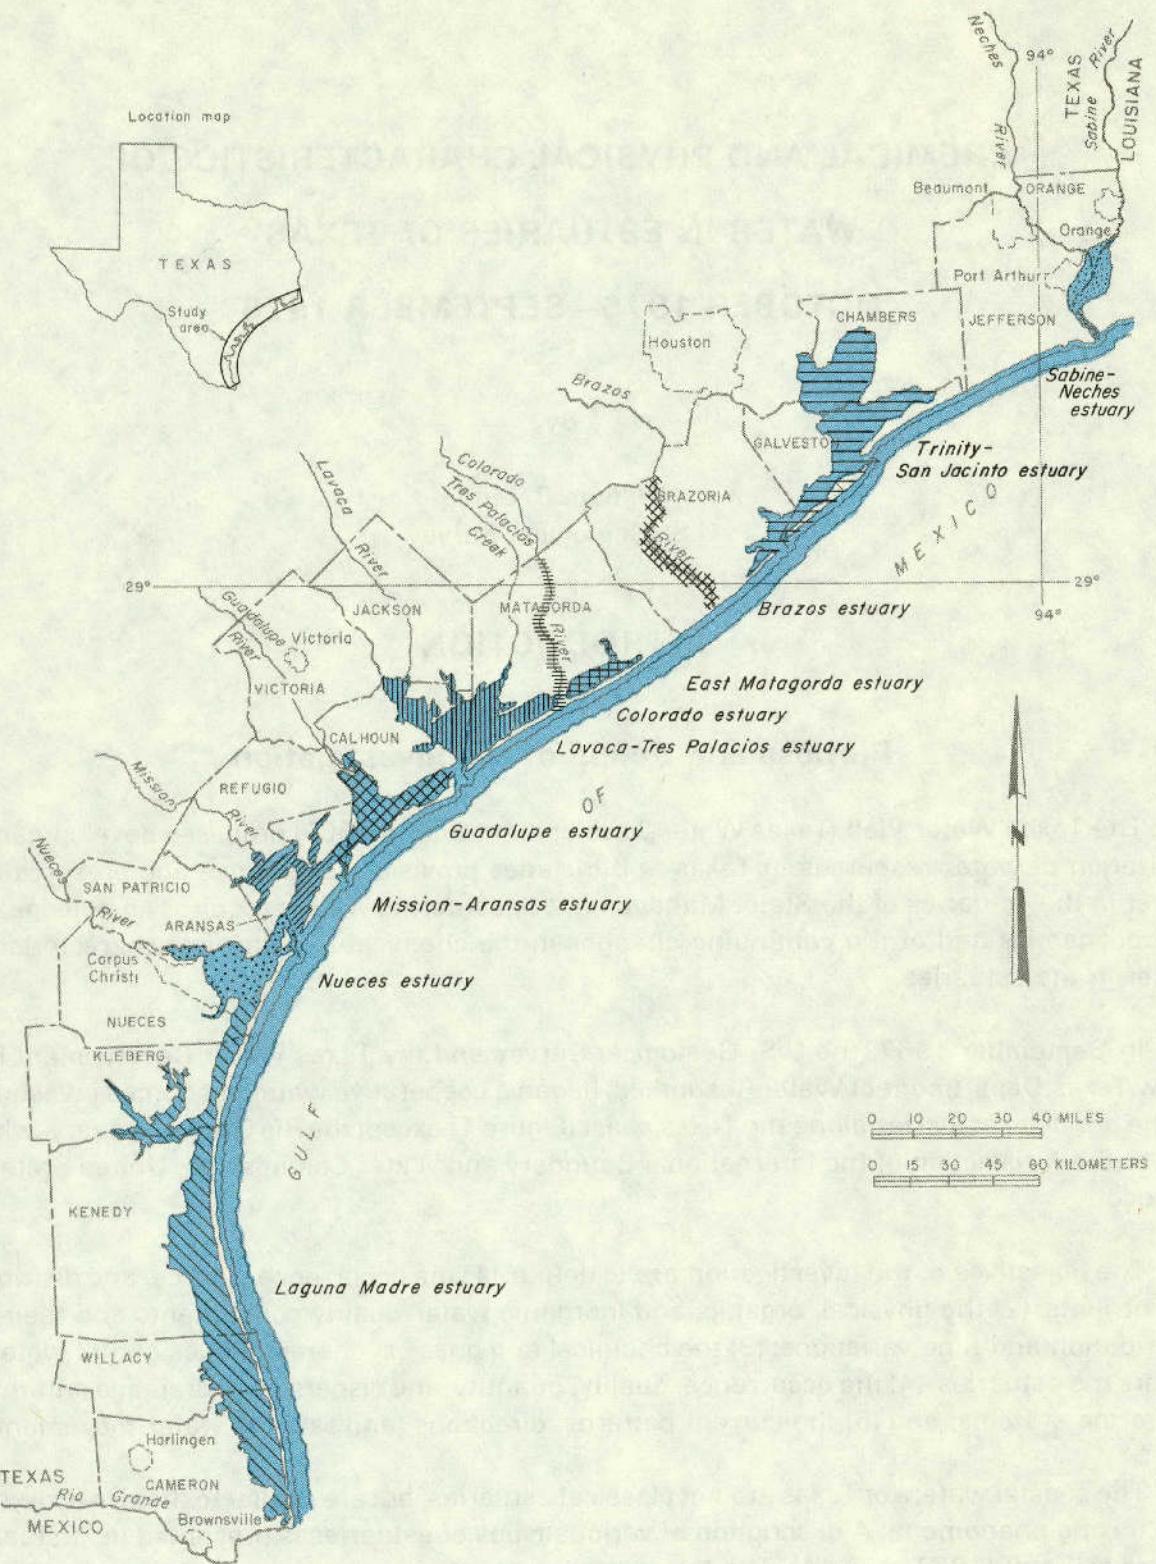

Figure 1  
Locations of the Estuaries

## **Status of the Project**

The first three objectives of the project are being met by a three-phased water-quality data-collection program of: (1) reconnaissance for establishment of an optimum data-collection network; (2) repetitive surveys throughout this network to determine the general chemical and physical characteristics of the estuarine systems; and (3) continued data collection at a reduced number of sites or at a reduced frequency to maintain definition of the chemical and physical characteristics of each estuarine system and of the relationship between systems. The first two phases have been completed and the third phase began in September 1973.

The fourth objective of the project is being met by data collection at six continuous streamflow-measuring stations and 11 stations at which monthly data on streamflow and water quality are obtained. The dispersion of water entering an estuary is being documented under the data-collection activities to meet the first three objectives.

The fifth objective of the project is being met by short-duration, intensive studies of inflow. Two such studies will be completed for each estuary. The studies on the Guadalupe estuary were completed in November 1970 and August 1973; the studies on the Lavaca-Tres Palacios estuary were completed in March 1971 and October 1972; the studies on the Mission-Aransas and Nueces estuaries were completed in November 1971 and May-June 1974; the studies on the Sabine-Neches estuary were completed in September 1974 and July 1975; and one study on the Trinity-San Jacinto estuary was completed in July 1976. These studies are providing data on inflow and exchange of water through the passes.

## **Previous and Related Reports**

This report, which presents data collected during water year 1976, is one of a series of annual basic-data reports that have been prepared since 1970 (Hahl and Ratzlaff, 1970, 1972, 1973, 1975; Ratzlaff, 1976; Lind and Ratzlaff, 1979; and Lind, 1980). A report by Grozier and others (1968, p. 47-61) includes data collected during flooding caused by Hurricane Beulah.

## **Metric Conversions**

Metric equivalents of English units of measurements are given in parentheses in the text. The English units used in this report may be converted to metric units by using the following conversion factors:

<u>From English units</u>	<u>Multiply by</u>	<u>To obtain metric units</u>
inch	2.54	centimeter (cm)
foot	.3048	meter (m)
mile	1.609	kilometer (km)
square mile	2.590	square kilometer ( $\text{km}^2$ )
cubic foot per second ( $\text{ft}^3/\text{s}$ )	.02832	cubic meter per second ( $\text{m}^3/\text{s}$ )

## Acknowledgments

The U.S. Army Corps of Engineers (Galveston District), the Texas Parks and Wildlife Department, and the Texas Department of Water Resources provided data and field assistance. Many private citizens and commercial fishermen furnished information on historical changes and existing conditions in the estuaries.

## DATA-COLLECTION METHODS

Approximately 170 data-collection sites were visited during the 1976 water year. About 50 percent of these sites are located adjacent to or between navigation aids, bridge piers, power poles, survey platforms, well structures, or other landmarks and can be reoccupied exactly. About 19 percent of the sites are close to shore features or reefs and are located by onboard radar or by compass heading and distance from the feature and water depth at the site; these sites can be reoccupied within 100 feet (30.5 m). About 31 percent of the sites are remote to any reference. They are reached by traveling from a known landmark at a known speed on a predetermined compass course. Verification of site location is made by checking the alignment of one or more distant landmarks by visual observation or by onboard radar. These sites can be reoccupied within 0.25 mile (0.4 km).

At each data-collection site, field data are collected from several points along a vertical. Samples for laboratory analyses are collected from a predetermined number of data-collection sites and at other sites in the network when significant changes in field data indicate a need for additional samples.

The properties or constituents that are measured in the field are dissolved oxygen (DO), specific conductance, temperature, pH, transparency by Secchi disk, and turbidity. Analyses conducted in the laboratory include the principal inorganic ions, biochemical oxygen demand (BOD), phenols, total organic carbon (TOC), dissolved organic carbon (DOC), suspended organic carbon (SOC), chlorophyll, insecticides and herbicides, ammonium, nitrite, nitrate, total phosphate, and other selected ions such as aluminum, arsenic, cadmium, chromium, cobalt, copper, iron, lead, lithium, manganese, mercury, nickel, strontium, and zinc.

## Field Instruments

The field instruments used in this investigation are given in the following table. The mention of the names of the manufacturers of the instruments is for identification purposes only and does not constitute an endorsement by the U.S. Geological Survey.

Parameter measured	Instrument	Model	Manufacturer
pH, dissolved oxygen, temperature, specific conductance	Surveyor	6	Hydrolab Corporation
pH	Specific ion meter	401	Orion Research

<u>Parameter measured</u>	<u>Instrument</u>	<u>Model</u>	<u>Manufacturer</u>
pH	pH meter	7417	Leeds & Northrup
Dissolved oxygen	Oxygen meter	54	Yellow Springs Instruments
Specific conductance	Solubridge	RB-3	Industrial Instruments
Temperature	Research thermometer	ET-100 Marine	Applied Research
Turbidity	Colorimeter	DR	Hach Chemical

The instruments used for pH measurements were calibrated daily during each water-quality survey by using three standards: pH 4.0, 7.0, and 10.0. The dissolved-oxygen meters were calibrated at least twice daily by using the oxygen-saturation data compiled by the American Public Health Association and others (1971, p. 480). The conductivity meters were calibrated periodically by using at least two standards in the conductivity ranges of the instruments. The electrical thermometer was calibrated weekly. The colorimeter was calibrated at each site. In addition, the pH and DO calibrations were rechecked at the end of each day.

### Treatment of Samples

All water samples except those for TOC, DOC, SOC, insecticide, and herbicide analyses were collected in plastic throwaway bottles. The BOD, TOC, phenol, and nutrient samples were chilled to about 1°C, stored in an ice chest, and shipped to the laboratory as soon as possible. Phosphoric acid (to pH 4) and copper sulfate were added to the phenol sample before chilling.

Samples for SOC and DOC analyses were collected in specially treated glass bottles and were filtered through 0.45-micrometer silver filters in the field. Residues on the filters for SOC analyses and filtrates for DOC analyses were chilled to about 1°C and shipped to the laboratory as soon as possible.

Chlorophyll samples were filtered through 0.45-micrometer membrane filters and the residues on the membrane filters were kept chilled until they could be analyzed.

Water samples for the principal dissolved inorganic anions, except carbonate and bicarbonate, were filtered through 0.45-micrometer membrane filters. Water samples for the principal dissolved inorganic cations, heavy metals, and other selected trace constituents, were filtered through 0.45-micrometer membrane filters into bottles prewashed with 10-percent nitric acid. Two milliliters of concentrated nitric acid were added to each liter of filtrate.

Suspended-sediment samples and bottom-sediment samples to be analyzed for herbicides and insecticides were collected in specially treated glass bottles, kept cool, and shipped air mail to the laboratory as soon as possible. Most herbicide and some insecticide samples were depth-integrated water samples; however, most insecticide and some herbicide samples were taken from bottom sediments. Most sediment samples were collected directly into a weighted sample bottle.

## **QUALITY OF WATER IN THE ESTUARIES**

### **Sabine-Neches Estuary**

The Sabine-Neches estuary, which has an area of about 100 square miles ( $259 \text{ km}^2$ ), consists of the tidal parts of the Sabine and Neches Rivers and other tributaries, Sabine Lake, the Sabine-Neches Canal, the Port Arthur Canal, parts of the Intracoastal Waterway, and Sabine Pass (Figure 2). Water depth at mean low water is greater than 40 feet (12.2 m) in dredged parts of the rivers, canals, and pass; about 15 feet (4.6 m) in the Intracoastal Waterway; and generally about 10 feet (3.0 m) in Sabine Lake.

Water-quality data (Table 1) were collected during October 1975 and February, April, June, July, and August 1976.

## **Trinity-San Jacinto Estuary**

The Trinity-San Jacinto estuary, which has an area of about 520 square miles (1,350 km<sup>2</sup>), consists of the tidal parts of the Trinity and San Jacinto Rivers and other tributaries, the Houston Ship Channel, part of the Intracoastal Waterway, Galveston Bay, East Bay, West Bay, and Trinity Bay (Figure 3). Water depth at mean low water is less than 10 feet (3.0 m) in East Bay, West Bay, and Trinity Bay. Galveston Bay is generally less than 10 feet (3.0 m) deep except near Bolivar Road where the depth increases to about 40 feet (12.2 m). The Houston Ship Channel is more than 40 feet (12.2 m) deep, and the Intracoastal Waterway is about 15 feet deep (4.6 m).

Water-quality data (Table 2) were collected during July 1976. Data for the San Jacinto River and for the upper part of the Houston Ship Channel are being collected by other agencies.

## Brazos Estuary

The Brazos estuary, which has an area of about 3 square miles ( $8 \text{ km}^2$ ), consists of the tidal parts of the Brazos River and parts of the Intracoastal Waterway (Figure 4). Although Freeport Harbor is not directly connected with the estuary, wastes from industrial operations around the harbor are discharged into the estuary. Water depth at mean low water is about 10 feet (3.0 m) in the river and about 15 feet (4.6 m) in the Intracoastal Waterway.

Water-quality data (Table 3) were collected during October 1975 and February and August 1976.

## East Matagorda Estuary

The East Matagorda estuary, which has an area of about 56 square miles (145 km<sup>2</sup>), consists of East Matagorda Bay, part of the Intracoastal Waterway, the tidal reaches of Caney Creek and Live Oak Bayou, and the tidal part of small tributaries (Figure 5). The maximum water depth at mean low water is 5 feet (1.5 m) in East Matagorda Bay and about 15 feet (4.6 m) in the Intracoastal Waterway.

Water-quality data (Table 4) were collected during October 1975 and February and August 1976.

## **Colorado Estuary**

The Colorado estuary, which has an area of about 2 square miles ( $5 \text{ km}^2$ ), consists of the tidal part of the Colorado River and part of the Intracoastal Waterway (Figure 6). The minimum depth at mean low water is about 6 feet (1.8 m) in the river channel and about 15 feet (4.6 m) in the Intracoastal Waterway.

Water-quality data (Table 5) were collected during October 1975 and February and August 1976.

## Lavaca-Tres Palacios Estuary

The Lavaca-Tres Palacios estuary, which has an area of about 350 square miles (907 km<sup>2</sup>), consists of the tidal parts of the Lavaca and Navidad Rivers, Tres Palacios Creek and other tributaries, Lavaca Bay, Cox Bay, Keller Bay, Carancahua Bay, Tres Palacios Bay, Matagorda Bay, Matagorda Bay Entrance Channel, Pass Cavallo, and part of the Intracoastal Waterway (Figure 7). Water depth at mean low water is 13 feet (4.0 m) or less in Matagorda Bay, except in the Matagorda Ship Channel, which is more than 40 feet (12.2 m) deep. Lavaca and Tres Palacios Bays are less than 8 feet (2.4 m) deep at mean low water, and Cox, Keller, and Carancahua Bays are less than 5 feet (1.5 m) deep. The rivers are generally less than 15 feet (4.6 m) deep.

Water-quality data (Table 6) were collected during October 1975 and February, April, June, and August 1976.

## Guadalupe Estuary

The Guadalupe estuary, which has an area of about 210 square miles (544 km<sup>2</sup>), consists of the tidal parts of the Guadalupe River, Mission Lake, Guadalupe Bay, Hynes Bay, San Antonio Bay, Espiritu Santo Bay, Mesquite Bay, Victoria Channel, and part of the Intracoastal Waterway (Figure 8). At mean low water, the Guadalupe River is about 10 feet (3.0 m) deep; Mission Lake, Guadalupe Bay, and Hynes Bay are less than 3 feet (1.0 m) deep; San Antonio Bay is less than 6 feet (1.8 m) deep; Espiritu Santo Bay is about 8 feet (2.4 m) deep; Mesquite Bay is about 4 feet (1.2 m) deep; Victoria Channel is more than 8 feet (2.4 m) deep; and the Intracoastal Waterway is about 15 feet (4.6 m) deep.

## Mission-Aransas Estuary

The Mission-Aransas estuary, which has an area of about 160 square miles (414 km<sup>2</sup>), consists of the tidal parts of Mission River, Aransas River, Copano Creek and other tributaries, Mission Bay, Copano Bay, Aransas Bay, St. Charles Bay, Carlos Bay, part of Redfish Bay, part of the Intracoastal Waterway, Lydia Ann Channel, and Aransas Pass (Figure 9). Water depth at mean low water is less than 2 feet (0.6 m) in Mission Bay, less than 8 feet (2.4 m) in Copano Bay, less than 13 feet (4.0 m) in Aransas Bay, less than 5 feet (1.5 m) in St. Charles Bay, 4 feet (1.2 m) or less in Carlos and Redfish Bays, about 15 feet (4.6 m) in the Intracoastal Waterway, about 20 feet (6.1 m) in the Lydia Ann Channel, and more than 40 feet (12.2 m) in Aransas Pass.

Water-quality data (Table 8) were collected during November 1975 and February, April, June, and August 1976.

## Nueces Estuary

The Nueces estuary, which has an area of about 200 square miles (518 km<sup>2</sup>), consists of the tidal parts of the Nueces River and other tributaries, Nueces Bay, Tule Lake Channel, Corpus Christi Bay, part of Redfish Bay, Corpus Christi Ship Channel, Aransas Pass, and part of the Intracoastal Waterway (Figure 10). Water depth at mean low water is less than 13 feet (4.0 m) in Corpus Christi Bay; less than 3 feet (1.0 m) in Nueces Bay; more than 40 feet (12.2 m) in Aransas Pass, Corpus Christi Ship Channel, and Tule Lake Channel; and about 15 feet (4.6 m) in the Intracoastal Waterway. A part of Redfish Bay is about 10 feet (3.0 m) deep, but about one-fourth of it is only 1 foot (0.3 m) deep at mean low water.

Water-quality data (Table 9) were collected during October 1975 and February, April, June, and August 1976.

## Laguna Madre Estuary

The Laguna Madre estuary, which has an area of about 640 square miles ( $1,658 \text{ km}^2$ ), consists of the tidal parts of Arroyo Colorado and other tributaries, upper Laguna Madre, Baffin Bay, lower Laguna Madre, Brownsville Ship Channel, part of the Intracoastal Waterway, Port Mansfield Entrance Channel, and Brazos Santiago Pass (Figure 11). At mean low water, upper and lower Laguna Madre and Baffin Bay are generally less than 4 feet (1.2 m) deep, but in a few areas are as much as 10 feet (3.0 m) deep. The Intracoastal Waterway, Port Mansfield Channel, and Arroyo Colorado are about 15 feet (4.6 m) deep; and the Brownsville Ship Channel is about 40 feet (12.2 m) deep.

Water-quality data (Table 10) were collected in October 1975 and February and August 1976.

**Figure 11**

# SELECTED HYDROLOGIC RECORDS

## Climatological Records

The climate of the region has a significant influence on the quality of the water in the estuaries. The types of climatological data available for an area about 60 miles (96.5 km) wide along the Texas coast are shown on Figure 12.

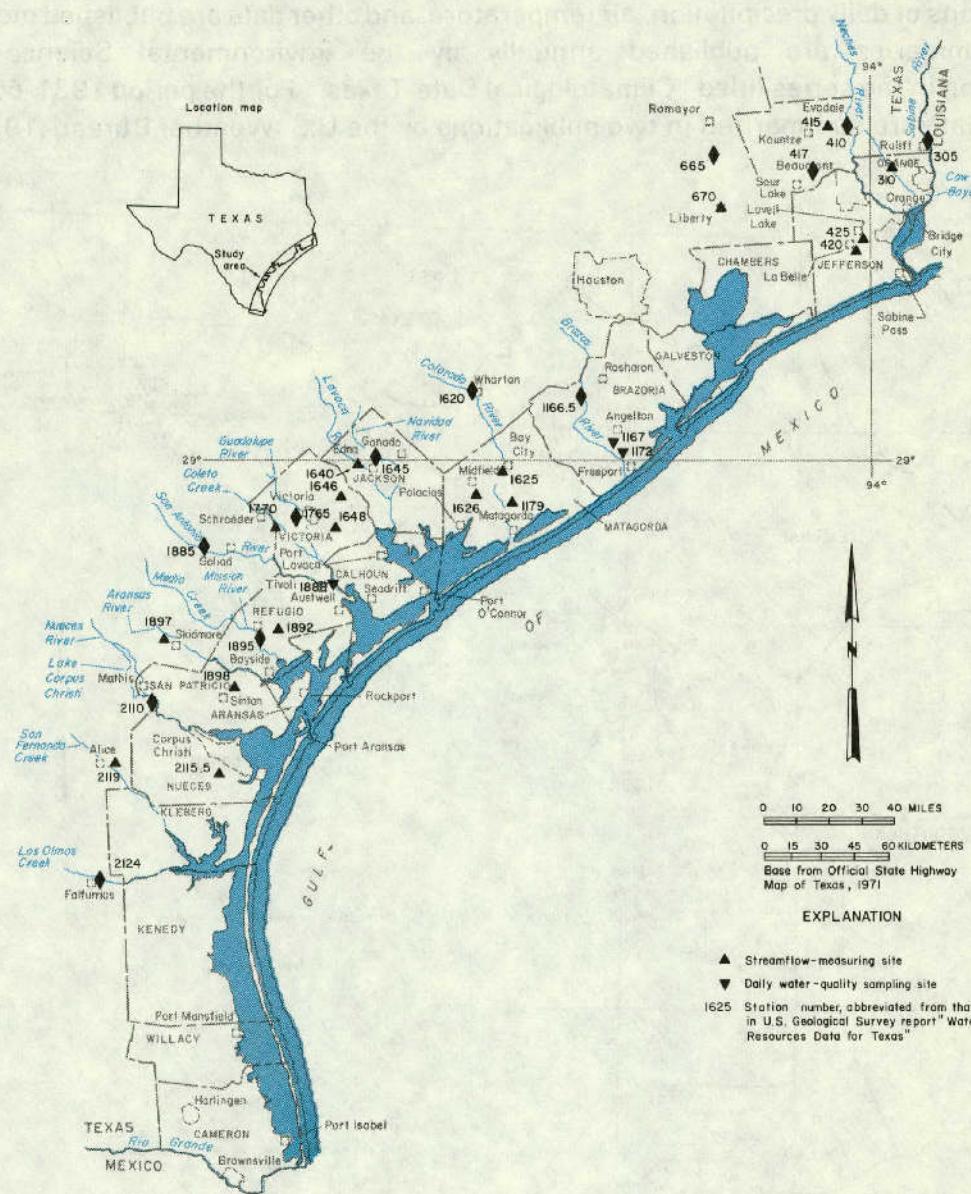

Tabulations of daily precipitation, air temperature, and other data are published monthly; and monthly summaries are published annually by the Environmental Science Services Administration in the series titled "Climatological Data-Texas." For the period 1931-60, monthly and annual data are summarized in two publications by the U.S. Weather Bureau (1958, 1965).

**Figure 12.—Locations of Selected Climatological Stations**

## Streamflow and Water-Quality Records

Streams along the Texas coast flow across the flat coastal plain and are incised below sea level; therefore, changes in water stage within the bays are often reflected for many miles up the tributary streams. Consequently, the farthest downstream sites at which continuous streamflow data can be obtained are located many miles upstream from the principal estuarine embayments. The locations<sup>1</sup> of the sites at which continuous streamflow and daily water-quality data are available are shown on Figure 13.

**Figure 13.—Locations of Streamflow-Measuring Sites and Daily Water-Quality Data-Collection Sites**

<sup>1</sup>Station numbers greater than 300 are abbreviated from the U.S. Geological Survey numbering system. For example, the two station numbers 08041500 and 08162650, in abbreviated form become 415 and 1626.5.

The streamflow data for these sites represent runoff reaching the coastal area, but do not describe all of the flow from streams that enter the estuaries. Intervening drainage, diversion for irrigation, return flows, and evapotranspiration may influence streamflow between the measuring sites and the estuaries.

Analyses of water collected daily at streamflow-measuring sites show the effects of geology and cultural development on runoff from the drainage basins. At times, however, return flows from irrigation, evapotranspiration, and lack of significant runoff from areas upstream result in altered water quality between the data-collection site and the estuary.

The drainage areas from which unmeasured runoff enters the estuaries range from less than 100 square miles ( $260 \text{ km}^2$ ) to more than 10,000 square miles ( $25,900 \text{ km}^2$ ). Periodic measurements indicate that during some seasons, unmeasured runoff that reaches the estuaries exceeds measured flow from the major tributaries.

To completely describe the quality and quantity of runoff from the entire area between continuous streamflow-measuring stations and the estuaries is not feasible; however, representative data are collected periodically at the sites shown on Figure 14.

Both continuous- and periodic-streamflow and chemical-quality data are published by the U.S. Geological Survey (1976).
