## ACKNOWLEDGEMENTS

We would like to express our appreciation to all those people from Texas Parks and Wildlife Department, National Marine Fisheries Service, Texas A\&M University's Sea Grant Program and the Instituto Nacional de Pesca of Mexico who have contributed to this program. Special thanks to Neal Baxter, Dr. Ed Klima and to each of the field party chiefs from NMFS - Dennis Emiliani, Gilbert Zamora, Jim Lyon, Steve Holloway, Bill Murdich, Greg Geischlag and Richard Christian-who participated in the tagging program.

We appreciate the efforts of Frank Patella and Daniel Patlan of NMFS for data processing and artwork contained in this report.

Thanks also go to C. E. Bryan, T. L. Heffernan, Roy Johnson and Patricia Johansen for reviewing the manuscript and offering valuable suggestions.

This study was conducted with partial funding from the U.S. Department of Commerce, National Oceanic and Atmospheric Administration, National Marine Fisheries Service, under P. L. 88-309 funds (Project No. 2-312-R)

## ABSTRACT

The Texas Parks and Wildlife Department and National Marine Fisheries Service conducted 14 mark-recapture studies to determine movement and growth of penaeid shrimp along the Texas coast. All shrimp were tagged with colored polyethylene streamer tags and released in inshore areas near Port Mansfield, Port Aransas and Port Isabel or in offshore waters near Port Aransas.

From May 1978 through July 1980, 101,699 shrimp were tagged; 96,842 were released. By November 1980, 2,906 shrimp had been returned for an overall recapture rate of $3,00 \%$. Recapture rates during inshore studies ranged from 0.00 to $16.32 \%$ while those for offshore releases ranged from 3.67 to $16.05 \%$. Pink shrimp were returned at higher rates than brown shrimp when released during the same study.

Over $89 \%$ of the shrimp from inshore releases and $74 \%$ of the shrimp from offshore releases were returned within 4 weeks. Over 94\% of al. 9 shrimp returned from inshore releases moved < 18 km . For offishore releases the overall percentage of returns moving < 37 km was $64 \%$ for brown shrimp, 56\% for pink shrimp and 65\% for white shrimp.

Returns indicated short-term movement in all directions with movement predominantly south and southwest from inshore releases at Port Isabel and alongshore to the northeast and south from offshore releases near Port Aransas. Long-term recaptures for brown shrimp (Penaeus aztecus) came from the south while pink shrimp (P. duorarum) and white shrimp (ㄹ. setiferus) were captured from both north and south.

Growth rates for individual shrimp were highly variable. For shrimp released inshore and free > 20 days growth rates for brown shrimp and pink shrimp were 0.268 and $0.287 \mathrm{~mm} / \mathrm{d}$ (tail length) respectively. For brown shrimp released offshore and free > 20 days growth rates were $0.282 \mathrm{~mm} / \mathrm{d}$ for June, July and August releases and $0.142 \mathrm{~mm} / \mathrm{d}$ for October releases.

## INTRODUCTION

As shrimping became an important fishery along the Atlantic and Gulf coasts of the United States after Wor Id War I, biologists soon realized the need for more information on the abundance, life history and population dynamics of the commercial penaeids. From 1935 to the late 1950's shrimp were tagged with small celluloid-disks affixed to the first abdominal segment with nickel pins (Lindner and Anderson 1956). These tags were similar to those used successfully for tagging fish since their invention by C. G. J. Petersen in 1894 (Rounsefell and Kask 1945).

In the late 1950's Dawson (1957) and Costello (1959) showed the penaeid shrimp could be marked with biological strains. Strain-injection was widely used in the 1960's by Klima (1964), Kutkuhn (1966), Costello and Allen (1966) and Clark et al. (1974). Techniques were further modified by Klima (1965) to identify classes with the use of fluorescent pigments and by Neal (1969) to identify individuals with small internal PVC tags. Marullo et al. (1976) developed a vinyl streamer tag for shrimp that has been slightly modified through the years into the small flexible polyethylene tag that is currently being used in the MEXUSGULF Shrimp Tagging Program by National Marine Fisheries Service (NMFS), Texas Parks and Wildlife Department (TPWD), Louisiana Wildlife and Fisheries Commission (LWFC) and the Instituto Nacional de Pesca of Mexico (INP).

Regional managment plans for the shrimp fishery of the Gulf of Mexico developed by the Gulf States Marine Fisheries Commission (Christmas and Etzold 1977) and the Gulf of Mexico Fishery Management Council (Van Lopik et al. 1979) acknowledge that for resource managers to recommend effective measures to utilize the annual yield of penaeid shrimp, it is essential that estimates of growth rates, mortality rates, migration patterns and maximum yield curves be developed. Tagging studies can provide some of the data necessary for these estimates.

The Texas Parks and Wildlife Department and National Marine Fisheries Service initiated mark-recapture studies in 1978 to determine movements and growth of penaeid shrimp stocks along the Texas coast.

## MATERIALS AND METHODS

The mark-recapture studies in Texas are cooperative efforts by the Texas Parks and Wildlife Department, National Marine Fisheries Service and Texas A\&M University Sea Grant Program. Species tagged were those most available within the predetermined release area.

All shrimp during 1978-1980 were tagged with colored polyethylene streamer tags similar to those described by Marullo et al. (1976). Tags were provided by NMFS and were 95 mm long, 3 mm wide and 4 or 6 mils thick depending on the size of shrimp to be tagged. Tags were notched to 2 mm near the center for a distance of 22 mm for better retention
in the shrimp. Tags were colored coded (orange, green, blue or black) and identified on each end by the letters "NMFS" and a 5 or 6 digit number (Figure 1).

A sewing needle with a slotted eye was attached through one end of each tag. For convenience and speed, consecutively numbered tags were aligned on a thin cardboard sheet and placed in front of each group of three or four "taggers" (Figure 2). Needles were dipped in a $10 \%$ concentration of Aureomycin in white petroleum jelly to retard infection in the tagged shrimp. The needle was inserted between the first and second abdominal segments and the tag was pulled through and centered in the shrimp. The tag was then removed from the needle. On large shrimp, needle-nose pliers were used to insert the needle and puil the tag through the exoskeleton.

Shrimp species, sex, tag number and tai] length were recorded before the shrimp was returned to a holding tank. Tail length measured from the anterior edge of the exoskeleton of the first abdominal segment to the tip of the telson was the standard measurement used in this program since tagged shrimp are sometimes headed by fishermen before the tag is noticed.

To enhance the return of recaptured shrimp, a fishing contest was implemented in which awards ranging from $\$ 50.00$ to $\$ 500.00$ were paid for recovered shrimp. Contest drawings were held periodically with eight winners being selected by computer. One award winner of $\$ 500.00$, one of $\$ 100.00$ and six of $\$ 50.00$ were selected during each drawing.

Through a contract with NMFS the Texas A\&M University Sea Grant Program was responsible for the awards system. Each individual returning a tagged shrimp with the required information received a letter acknowledging his participation in the program and explaining the cash award contest pool (Appendix A). "Certificates of Recognition" are presented to fishermen who return 10 or more tagged shrimp (Appendix B) and distribution by NMFS of "The Gulf Streamer", a NMFS shrimp tagging news letter, is distributed to interested parties (Appendix C).

Tagged shrimp were returned to port agents and biologists located in major ports. In addition to collecting catch and effort statistics, these agents collect recovered tagged shrimp and obtain and verify pertinent information on area and date of recapture. Contest posters (Figure 3) showing the location of the tag in the shrimp were placed at major ports to acquaint fishermen with the tagging program and type of tag being used. Posters also gave instructions on the handling of shrimp and reporting of the required recapture information for eligibility in the contest. Posters were distributed in English, Spanish and Vietnamese (Figure 4).

All release and recovery data for recaptured shrimp were processed by NMFS personnel at the Galveston Laboratory or by agents at the major shrimping ports. NMFS compiled the tag return data as part of their MEXUS-GULF Program and supplied the information to the cooperating agencies.

The TPWD research vessel Western Gulf was used during the offshore studies as a tagging facility and to obtain, transport and/or release tagged shrimp. Holding tanks, aerators and other tagging gear were provided by TPWD and NMFS. Manpower for the capture, tagging and retease was provided by TPWD and NMFS with assistance during 1978 from the Instituto Nacional de Pesca.

During offshore studies $10-20$ min tows were made with a standard 12.2-14.3 m shrimp trawl to capture live shrimp. As the contents of the net were dumped on the deck, live shrimp were quickly transferred to 1893-1 tanks with circulating water. Holding tanks and tagging equipment were similar to those described by Emiliani (1971).

Every effort was made to insure that shrimp to be tagged were maintained in healthy condition. When large numbers of organisms were caught a preliminary culling of live shrimp into galvanized wash tubs was used to reduce stress on the shrimp. Aboard the Western Gulf compressed air was bubbled through air-stones to provide additional aeration to the flow-through water system. Shrimp were usually held at least 6 h to allow them to recover prior to tagging. Periodic culling of dead and unhealthy shrimp reduced water fouling and stress on remaining shrimp.

After tagging, the shrimp were held for $3-6 \mathrm{~h}$ to determine tagging mortality. To protect tagged shrimp during offshore releases they were placed in expendable canisters (Emiliani 1971) and released at approximately $0.8-\mathrm{km}$ intervals while the vessel was underway. The canisters sank to the bottom, opened after 10-12 min and released the shrimp.

The tagging procedure for inshore and offshore studies was basically the same, but there were some differences in capture and release methods. Except for the Rockport-Port Aransas studies during 1978 all shrimp for inshore releases were purchased from local bait dealers in the study area. Inshore and shallow-water releases during 1978 were made with sections of flexible dryer hose ( 102 mm dia). All tagged shrimp during 1979 and 1980 inshore studies were transported by skiff from the tagging site to the release area and released by hand in water $<1.25 \mathrm{~m}$ deep.

Changes in procedures during the first two years were detailed by Cody and Rice (1979) and Cody and Avent (1980). The only changes to proposed procedures during the third year were to conduct two inshore studies along the lower Texas coast during March-April instead of one during May. Both studies were completed earlier in the spring than previous studies, which shifted emphas is from brown shrimp (Penaeus aztecus) to pink shrimp ( P . duorarum).

In analyzing shrimp return data all recoveries were included, with the exception of those in which recovery data were lacking or were obviously erroneous.

## RESULTS

All tagging studies proposed during the first three years were completed as scheduled. The time frame for some of the studies was changed to take advantage of the availability of shrimp and weather conditions conducive to successful releases. Overall, 50,000 shrimp were to be tagged during 1978, 30,000 during 1979 and 25,000 during 1980; 49,186 shrimp were tagged during 1978, 32,602 during 1979 and 19,911 during 1980 (Table 1).

## Releases and Returns

From 1978 through 1980, 101,699 brown shrimp, pink shrimp and white shrimp (ㄹ. Setiferus) were tagged and 96,842 ( $95.2 \%$ ) were released (Table 1). The percentage released each year was relatively constant -- $94.6 \%(46,510)$ during 1978, $96.1 \% ~(31,333)$ during 1979 and $95.4 \%(18,999)$ during 1980. Short-term tagging mortality for individual studies averaged $4.4 \%$ and ranged from 2.1 to 8.3\%. Release areas are shown in Figure 5.

By 17 November 1980, 2,906 tagged shrimp (3.00\%) had been recaptured and returned; 1,792 (2.13\% return rate) were from inshore releases and 1,144 (8.11\% return rate) were from offshore releases (Table 1). Seven returns were from inshore releases during 1978, 223 were from inshore releases during 1979 and 1,532 were from inshore releases during 1980 . A total of 347 tagged shrimp was returned from offshore releases during 1978 and 495 were returned from offshore releases during 1979. Preliminary returns from offshore releases during 1980 totaled 302 shrimp.

Tag return rates for inshore releases ranged from 0.00 (June-July, 1979) to $16.32 \%$ (March 1980) and return rates for offshore releases ranged from 3.67 (June 1980) to $16.05 \%$ (October 1979) (Table 1).

Return rates by species show that pink shrimp were consistently returned at higher rates ( 4.66 to $25.00 \%$ ) than brown shrimp ( 0.09 to 7.69\%) for inshore releases during 1979 and 1980 (Table 1). The overall return rate for offshore releases was 7.34\% for brown shrimp and 7.73\% for pink shrimp. For individual offshore releases brown shrimp return rates were highest during October 1978 (10.26\%), September 1979 (19.75\%) and October 1979 (19.86\%).

Time Free
Over $78 \%$ of the shrimp from inshore releases were returned during the first 2 weeks and 89\% were returned during the first 4 weeks (Table 2). The only exception was May-June 1979 when $64 \%$ (7) of the shrimp were returned after 1-3 mo, which corresponds with the end of the closed season in the Gulf. When nearly equal numbers of brown shrimp and pink shrimp were released the return patterns for both species were similar. No shrimp from inshore releases were returned after I year.

For offshore releases $57 \%$ of the shrimp were returned during the first 2 weeks and $74 \%$ were returned during the first 4 weeks (Table 2). July 1980 releases had the lowest percentage returned after 4 weeks, probably due to reduced fishing effort caused by Hurricane Allen. The
percentage of returns during the first 4 weeks ranged from 70 to $90 \%$ for other offshore releases. The only shrimp returned after a year of freedom were from releases during August and October 1978.

No shrimp were returned during the first week after June 1980 releases (Table 2). Most of the returns from this release ( $60 \%$ ) were made during weeks 3 and 4 which correspond with the end of the closed Gulf season.

Except when the number of returns was very low, brown shrimp, pink shrimp and white shrimp released during the same study showed similar return patterns.

## Distance travelled

Over 94\% of all shrimp returned from inshore releases moved < 18 km (Table 3). Only 10 shrimp ( $0.6 \%$ ) moved $>185 \mathrm{~km}$. Pink shrimp appeared to move sifghtly more than brown shrimp released during the same study.

Shrimp released in offshore waters moved more than those released in inshore waters. Only $47 \%$ of all shrimp returned from offshore releases moved < 18 km (Table 3). For individual releases the percentage moving $<18 \mathrm{~km}$ ranged from 27 to $74 \%$. Of the total returns $20 \%$ moved $93-185 \mathrm{~km}$ and $3 \%$ moved $>185 \mathrm{~km}$. A total of 28 brown shrimp, 2 pink shrimp and 5 white shrimp moved > 185 km .

Tagged shrimp released offshore during August, September and October appeared to move less than those released during June and July. For shrimp released during August-0ctober the percentage moving $>92 \mathrm{~km}$ ranged from 9 to $16 \%$ (Table 3). For shrimp released during June-July the percentage moving $>92 \mathrm{~km}$ was 27 to $60 \%$.

The overall percentage of returns moving < 37 km was similar for brown shrimp (64\%), pink shrimp (56\%) and white shrimp (65\%) during offshore releases (Table 3). There appeared to be some differences in long-range movement between species. Over $25 \%$ of the brown shrimp, $36 \%$ of the pink shrimp and $12 \%$ of the white shrimp returned moved 92 km .

Direction travelled
Shrimp returned from inshore releases moved mainly $E, S E, S, S W$ and $W$ (Table 4). During 1979, $88 \%$ of the returns from releases at Port Isabel moved E, SE, $S$ or $W$. During 1980 when tagged shrimp were released earlier in the year than in 1979, $85 \%$ of the returned shrimp moved $S$ or SW. Brown shrimp and pink shrimp appeared to move in similar directions for each inshore release.

Shrimp returned from offshore releases moved mainly NE, E, SE, S and SW (Table 4). Over 65\% of the returns from releases during August, September and October were from the NE, $S$ and $S W$. Altogether $84 \%$ of the returns from June and July releases were from the $E, S E, S$ and $S W$.

For all offshore releases combined $33 \%$ of the brown shrimp, $40 \%$ of the pink shrimp and $60 \%$ of the white shrimp moved N, NE or $E ; 63 \%$ of the brown shrimp, $60 \%$ of the pink shrimp and $26 \%$ of the white shrimp
moved $S E, S$, or $S W$. moved $\mathrm{SE}, \mathrm{S}$; or SW .

Brown shrimp and pink shrimp free for $\leq 20$ days showed more variability in growth/day than shrimp free for $>20$ days. The mean growth/ day (tail length) for brown shrimp released inshore and free for 0-10 and $11-20$ days ranged from -0.023 to 0.107 mm (Table 5). Mean growth/ day for pink shrimp free $0-10$ and 11-20 days ranged from -0.067 to 0.752 mm . After 20 days, growth rates ranged from 0.195 to $0.450 \mathrm{~mm} / \mathrm{d}$ for brown shrimp and 0.209 to $0.384 \mathrm{~mm} / \mathrm{d}$ for pink shrimp when $>1$ shrimp was returned per period.

Combining all recoveries from April 1979 and 1980 releases the mean growth/day for brown shrimp free > 20 days was 0.268 mm ( 19 returns; mean size 50 mm at release). Combining April 1979, March 1980 and Apri? 1980 releases the mean growth/day for pink shrimp free $>20$ days was 0.287 mm (203 returns; mean size 53 mm at release).

For offshore releases the mean growth/day of brown shrimp free $0-10$ and $11-20$ days ranged from -0.013 to 0.919 mm (Table 5). After 20 days mean growth rates ranged from 0.008 to 0.420 mm . Mean growth rates for white shrimp ranged from 0.079 to $0.226 \mathrm{~mm} / \mathrm{d}$ after release in September 1979.

Combining August 1978, June 1980 and July 1980 releases the mean growth/day for brown shrimp free > 20 days was 0.282 mm ( 173 returns; mean size 67 mm at release). Combining October 1978 and 0ctober 1979 releases the mean growth/day for brown shrimp free $>20$ days was 0.142 mm ( 188 returns; mean size 77 mm at release).

## DISCUSSION

Inshore return rates for 1978 and 1979 were $<2.5 \%$. Procedures used during the two years, changes in the release methods and possible reasons for the poor results are discussed in Cody and Avent (1980).

Increased return rates for inshore studies during 1980 may be the result of an attempt to increase the quality of shrimp released, tagging only 1,000 shrimp per day, scheduling the releases when water temperatures were lower (20.7-21.0 C) than in 1978 and 1979 ( $25.8-31.3 \mathrm{C}$ ) and a change in the fishing pattern of the Port Isabel bait shrimpers who recaptured most of the tags. Before 1980 most trawling was done in the Brownsville Ship Channel and the Turning Basin at Port Isabel. During 1980 more boats entered the bait shrimp fishery and because of dredging in the Ship Channel nearly all effort was concentrated in the Turning Basin. Many of the tagged shrimp released in the Laguna Madre followed the ICWW through the Turning Basin on their migration route to the Brownsville Ship Channel and the Gulf of Mexico.

Because there were only 4 shrimp returned out of 47,918 released inshore near Port Aransas and Aransas Pass during 1978 and 1979, the procedure of releasing shrimp in shallow inshore waters was replaced with a plan to capture and release shrimp in the shallow Gulf of Mexico. The theory being that most of these shrimp would be recent migrants from the bays and would already be adjusted to the Gulf environment.

Preliminary results indicated return rates for offshore releases during 1980 would not be as high as during 1978 and 1979. However, return rates were higher (3.67-5.00\%) than for any previous June or July release ( $0-0.12 \%$ ). Short-term recovery rates were lower than usual during June and July 1980 due to the closed season in the Gulf and little. fishing effort in the immediate area.

Cooperative tagging studies by TPWD and NMFS in Texas during 1980 had the highest return rates of all the MEXUS-GULF releases. Return rates for releases at Port Isabel totaled $12.41 \%$ while rates for other inshore releases ranged from $0.01 \%$ (San Luis Pass-LGL) to $10.53 \%$ (Calcasieu Lake-LGL) (NMFS unpublished data). The return rate from 1980 offshore releases in Texas totaled $12.60 \%$ and compared favorably with return rates from Mexico (17.66\%), Mississippi (8.76\%), Alabama ( $6.80 \%$ ) and Louisiana (6.74\%) (NMFS unpublished data).

Many tagged shrimp released during 1978-1980 were returned within the first two weeks after release, a pattern which has also been reported by Klima (1964) and Compton and Bradley (1962). Klima reported more than 90\% of the recoveries from releases near Galveston, Texas and Grand Isle, Louisiana were returned within 10 days. Compton and Bradley reported most of the returns from the Aransas area were within 2 weeks.

Klima (1964) reported that the distance moved did not increase with increased time at large and that most brown shrimp returns from. Texas during 1962 were within 30 miles of the release site. No consistent relationship between distance moved and time free was observed during 1978-80 release.

Movement of tagged shrimp may be related to prevailing currents along the Texas coast which flow predominantly to the northeast or to the south depending on the time of the year. Previous Texas studies by McRae (1952) and Compton and Bradley (1962) reported southward movement of tagged shrimp, which is a characteristic of this study and other MEXUS-GULF studies along the south Texas coast.

Growth for individual shrimp was highly variable. When analyzing return data for growth, there appears to be several problems inherent in the measurement of shrimp on release and on return which may affect individual growth/day calculations. Shrimp free only a few days often had negative growth rates. Some of the variation may be explained by shrinkage of shrimp due to drying, freezing and/or preservation in formalin (McCoy 1972) and some may be due to improper measurement during the tagging process. Moulting of shrimp shortly after tagging and release may explain why growth was sometimes $>5 \mathrm{~mm} / \mathrm{d}$.

Factors such as size of shrimp at release, area of release, month of release and water temperature can affect the growth rate of tagged shrimp and make comparisons difficult. Knudsen et al. (1977) discussed some of these difficulties in comparing mark-recapture experiments.

Another problem in comparing our growth data to previous studies is our use of tail length instead of total length for all measurements. Using total length-tail length conversion tables prepared by Fontaine
(1971), total length growth estimates for inshore releases were $0.427 \mathrm{~mm} / \mathrm{d}$ for brown shrimp and $0.478 \mathrm{~mm} / \mathrm{d}$ for pink shrimp. Brown shrimp growth rates estimated by Knudsen et a1. (1977) for releases in a Louisiana coastal marsh ranged from 0.52 to $0.87 \mathrm{~mm} / \mathrm{d}$. Offshore growth rates for brown shrimp were comparible to inshore growth rates during the summer ( $0.469 \mathrm{~mm} / \mathrm{d}$ ) but were considerably less during the fall ( $0.238 \mathrm{~mm} / \mathrm{d}$ ).

The validity of conclusions based on mark-recapture experiments depends on the accuracy of the recovery information. All participants in the recovery phase make every effort to obtain detailed and accurate information on recaptured shrimp. Nevertheless, caution should be exercised when drawing conclusions based on very few recoveries. For this reason the best data available are those from inshore releases at Port Isabel during 1979 and 1980 and from offshore releases during 1978, 1979 and 1980.

Preliminary results on the movement and migration of tagged shrimp recovered from MEXUS-GULF Shrimp Tagging Studies have been presented at various conferences and meetings in the United States and Mexico by NMFS and TPWD personnel.

The cooperative mark-recapture studies of penaeid shrimp in Texas are an integral part of the MEXUS-GULF Shrimp tagging program being conducted by fisheries departments from the United States and Mexico. Data obtained from the releases of tagged shrimp in the western Gulf of Mexico will provide valuable information for resource managers of this extremely valuable fishery.

Figure 1. A. Tagged shrimp showing placement of polyethylene streamer between abdominal segments. B. Drawing of tag showing actual size.

Figure 2. Diagxam of 3-tank system and tagging table used for holding and tagging penaeid shrimp.

Awards will be randomly selected from tagged shrimp that are returned. To qualify as an entry, the tag must be in the shrimp and the date and location the shrimp was caught must be given. Sets of awards will continue into 1979. Any tag number that hasn't been chosen remains eligible in the later drawings.

## SHRIMP AND GROUNDFISH RESEARCH NEWS

## Mexus-Gulf Projest

The 1980 objectives for the MEXUS-G1.in; , jject were to determine migration, rates of growth, and mortality of pink, white, and brown shrimp as well as to define fishing characteristics and fishing effort by U.S. and Mexican floets. Data obtained during 1978-1979 co-operative shrimp studies have been analyzed and results were presented at the MEXUS-GULF meeting in Tampico, Mexico, in October.
Shrimp research in the Gulf of Mexico had its first major emphasis in the late 1950's. In 1976 the Fisheries Conservation and Management Act extended U.S. jurisdiction to 200 miles from the coastline. At present, the NMFS shrimp research program is aimed at documenting geographical boundaries of the stock and developing noodels which can predict potential yield under varying .shing efforts.
A plastic streamer was developed for use as a tag in shrimp marking experiments at the NMFS Galveston Laboratory. With modification and more testing, the Mini-Ribbon tag proved successful in allowing individual identification of shrimp from small (200 to the pound) animals to farge, sexually mature adults. Previousiy, smaller shrimp had not been successfully tagged and released. Simultaneously, U.S. and Mexico began developing a cooperative plan that eventuaily turned into Ptoject MEXUS-GULF, an international program encompassing the fisheries of the Gutf of Mexico.

Cooperative shrimp mark and recapture studies using the Mini-Ribbon tag have now resulted in combined studies off the east coast of Mexico for three years with ahother combined study planned in March of 1981.

Other countries have now begun to use the Mini-Ribbon Tag. Kuwait initiated a shrimp tagging program in 1979 and the NMFS Laboratory at Galveston has recently assisted in developing a plan, to be initiated in 1981, for the South American countries of Brazil, French Guiana, and Surinam to conduct cooperative studies on their
shrimp fisheries, using the Mini-Ribbon Tag and techniques develoner at the galveston Laboratory. Tagging experimentis provide much of the Information needed for stock assessment such as growth, mortality, and migration of shrimp.
Results of a shrimp tagging cruise off Port Aransas, Texas in July 1980 are shown in the Figure below. Numbers of recoveries plotted in ten minute grids are shown by recapture location.

The next contest drawing will be held in January. The contest is conducted to enhance the interest of shrimp fishermen in returning tagged shrimp. The primary factor in the success of the project is the continued cooperation of the shrimp fishery.

## 1980 Shrimp Tagging to Date

In 1980, tagging experiments were accomplished off Mexico and the Gulf States of Texas, Loulsiana, Mississippl, and Alabama, as shown in the figure below.

Of the studies along the four states in 1980, the Texas study was the largest in numbers of shrimp released, with a total release of 66,768 tagged shrimp in five areas. In Mexico, there were two release areas with a total of 16,397 shrimp released. Shrimp were released in six areas along Louisiana, Mississippi, and Alabarna with a total of 22,030 tagged shrimp released.

NMFS has tagged all three commercial species in 1980: brown, pink and white shrimp. Pink shrimp, however, yielded the highest recapture percentages. Combining Mexico and the state of Texas, the number of pink shrimp tagged and released was 19,589 and the number recaptured totaled 2,559 , with a recapture percentage of 13 percent. The number of brown shrimp released was much higher than that of pink shrimp, yet the number of brown shrimp recaptured was slightly less than that of pink shrimp, yielding a much lower recapture percentage for brown shrimp. The number of brown shrimp tagged and refeased was 63,385 and the number recaptured to date is 2,459 , representing a recapture percentage of four percent.

White shrimp represented the lowest number of tagged animals released. The largest number of white shrimp was released off the Mississippi-Alabama coast. White shrimp were also released off Louisiana and Mexico. The totat number of white shrimp released is 11,734 and thenumber recaptured to date is 551 . Recapture percentage of white shrimp to date is five percent.

The NMFS urges everyone, commercial and sportfishermen alike, to remain active in the tagged shrimp return program. The study will not be effective unless all tagged shrimp caught are returned with: name of fisherman, location of capture, (loran reading and depth) and date. We greatly appreciate your help in returning tagged shrimp.

The table on shrimp tagging studies contains the number of each species released, recaptured, and the percentages recaptured. The table is arranged by states of release.

## 1980 Shrimp Fishing Contest Winners

The last shrimp contest drawings for 1980 were held in September and November. Cash awards were presented to the following fishermen with our congratulations.

# Bottomfish Research Program-1980 

The trawl fisheries of the Southeast region harvest two major faunal groups: shrimp and bottom fish. The directed bottomfish trawl fishery, centered in the central Gult, exploits approximately 250 species of fish. However, Sclaenidae (croakers, spot, and sea trout) account for approximately $75 \%$ of the total tish production. The directed bottomfish trawl fishery also catches a small percentage of shrimp as by-catch. On the other hand, the shrimp fishery catches and discards up to 900,000 tons of bottomfish annually.
In the early 70's a major research effort was instituted by the Pascagoula Laboratory to evaluate and assess the bottomfish stocks of the Gulf of Mexico. In the Northern Gulf, there have been a series of assessment cruises which have provided information on bottomfish distribution, species composition, and measures of abundance.

Of all the bottomilsh, the most important species is croaker, the preferred species of the industry. (Recently we have been working on methods of tagging Atlantic croaker. Different types of tags are being tested to see which is most efficient and best sulted for the fish).

Highest densities of ground fish occur in the area of the Northern Gulf of Mexico between Point Au Fer, Louisiana and Perdido Bay, Florida. The fisheries operate al", st entirely within this area in depths out to $90 \mathrm{~m}(50 \mathrm{tm})$.
