ACKNOWLEDGEMENTS

The authors wish to recognize the following individuals for their valuable assistance and contribution to the completion of the research reported herein:

Weslaco Research and Extension Center:

Mr. John Drawee: Special Projects
Dr. John Norman: Extension Agent-Entomology
Mr. Dwight Rockers: Farm Research Services Manager

Kingsville:

Mr. Cliet Lowman: Manager - King Ranch Farms
Mr. Scott Moody: Consultant - King Ranch Farms

Nueces County:

Mr. Harvey Buehring: County Extension Agent
Mr. Robert Swize: Demonstration Assistant
Mr. Kenneth Schaefer: Research Associate - Corpus Christi
Mr. Don Hoelsher: Hoelscher Farms

Corpus Christi Research and Extension Center:

Mr. Kenneth Schaefer: Research Associate

San Patricio County:

Mr. Darwin Anderson: County Extension Agent
Mr. James Adams: Adams Farm

Matagorda County:

Mr. James Engbrock: County Extension Agent
Mr. Don Batchelder: Batchelder Farms
Mr. Ken Batchelder: Batchelder Farms
Mr. Brad Batchelder: Bathchelder Farms

College Station:

Mr. Al Nelson: Research Farm Manager
Mrs. Rhonda Thorson: Secretary
Miss Anna Alaniz: Student Worker
Mr. Doug Dunn: Student Worker
Mr. David Hortenstine: Student Worker
Mr. Devin Keischnick: Student Worker
Mr. Ed Radford: Student Worker
Mr. Tim Sloat: Ag. Res. Tech I
Miss Holly Weathersby: Student Worker

Stiles Foundation Farm (Thrall):

Mr. Calvin Rinn: Farm Manager

Uvalde County:

Dr. Noble Kearney: Extension Agronomist

Mr. Lawrence Friesenhahn: Friesenhahn Farms

Uvalde Research and Extension Center:

Dr. Haile Tewolde: Research Associate

Dallas Research and Extension Center:

Mr. Bill Langston: Research Associate

Mr. David Adams: Farm Research Service

Chillicothe-Vernon Research and Extension Center:

Mr. Truett Moore: Research Associate

Cotton Cultivar Tests for 1990 in Central and South Texas

**C. W. Smith, B. Bredthauer,
and E. Clark**

Cotton cultivar tests (CCT) are conducted each year by the Texas Agricultural Experiment Station to determine the relative performance of cultivars (varieties) available to producers in Texas. These tests are conducted statewide to evaluate commercial cultivars in every cotton growing region. Since Texas is a large state with diverse climates and growing seasons, the CCT results are reported separately for Central and South Texas, the Rolling and High Plains, and Far West Texas. This report concentrates on the cotton production regions of Central and South Texas.

Because of the growing interest in Pima cotton production in Texas, a Pima strain test was grown near Uvalde in 1990. This test consisted of 5 experimental Pima strains, Pima S-6, the commercial Pima cultivar, and Deltapine 20.

Test locations, soil types, planting dates, and first-harvest dates are given in Table 1, with yield and fiber characteristics presented in Tables 2 - 19. Latest two-year and three-year averages are shown in Tables 20 - 33 for cultivars grown at each location during the period 1988-1990. Results from the Pima Strain evaluation are shown on Tables 34 and 35.

Yield and other characteristics were analyzed as randomized complete blocks. Least Significant Differences (LSD) were used to determine if two cultivars were significantly different at $k = 100$, which approximates the 5% probability level. Values reported for any two cultivars that differ by more than the LSD value are expected to be different in 95 of every 100 comparisons. The test average (mean) and the coefficient of variation (CV) also are reported for each characteristic measured at each location. The coefficient of variation is a measure of the uniformity of the test site (e.g. soil uniformity, drainage, disease, etc.). The lower the coefficient of variation, the more reliable the test results.

Agronomic Determinations

Lint yield: Lint yield per acre is determined as follows: (lbs. seedcotton/plot) \times (appropriate lint percent) \times (area conversion factor).

Percent lint: Amount of lint in a random boll sample expressed as a percent of the seedcotton in the sample.

Boll size: The number of normal bolls occurring in the middle of the fruiting zone required to produce one pound of seedcotton.

Fiber Quality Determinations

Fiber quality parameters were determined by high volume instrument (HVI) testing at the Texas Tech International Textile Research Center in Lubbock, TX.

Fiber Fineness: Fiber fineness, micronair, is a measure of the maturity and/or the fineness of cotton fibers and is reported in micronaire units. Micronaire is a relative measure of the development of the secondary cell of the cotton fiber throughout its entire length. Processing rates, fabric dyeing, and yarn and fabric appearance are adversely affected by immature fibers. Fine fibers, although mature, weigh less per unit length and require reduced processing speeds compared to thicker fibers; yet, these finer fibers produce stronger yarns. Thick or coarse fibers result in fewer fibers in a cross section of yarn, and therefore, produce weaker yarns.

Fiber fineness is determined by forcing air through a specified weight of lint. The rate of air flow is related to fiber thickness. Finer fibers result in more fibers per specified weight and, therefore, have greater resistance to air flow. Micronair values of 3.4 or below indicate fine and usually immature fibers, and values of 5.0 or higher indicate coarse fibers. Values of 3.5 to 4.9 are desirable and indicate mature, well-developed fibers.

Fiber length: Fiber length is reported in hundredths of an inch as measured by a fibergraph instrument and is the average of the longest 50 percent of the fibers in the sample. Long fibers are desirable because they produce greater yarn strength, aid in spinning finer yarns, and can be processed at higher speeds.

HVI fiber lengths and descriptive designation

Below 0.97	Short
0.97 - 1.10	Medium
1.11 - 1.28	Long
Above 1.28	Extra long

Fiber Strength: Yarn strength and ease of processing are positively correlated with strong-fibered cottons. Strength values are reported in grams of force required to break a bundle of cotton fibers with the holding jaws separated by 1/8 inch. The size of the bundle of fibers is described in tex units. Fiber strength is classified from very low to very high.

HVI 1/8-inch gauge strength (grams/tex)	Fiber length group and descriptive designation
	<u>Short</u> (0.96 inch or less)
18-19	Very low
20-21	Low
22-23	Average
24-25	High
26-27	Very high
	<u>Medium</u> (0.97-1.10 inch)
17-19	Very low
20-22	Low
23-25	Average
26-28	High
29-31	Very High
	<u>Long</u> (1.11-1.28 inch)
18-20	Very low
21-23	Low
24-26	Average
27-29	High
30-32	Very high

Fiber Uniformity: Fiber uniformity index (UI) provides a relative measure of the length uniformity of cotton fibers. Uniformity is calculated as the ratio of the average length of all fibers to the average length of the longest 50 percent of the fibers in the sample. The ratio is multiplied by 100 to convert uniformity to a percentage basis. High uniformity values indicate uniform fiber length distribution and are associated with a high-quality product and with low manufacturing waste.

Uniformity ratios
and descriptive designation

Below 77	Very low
77-79	Low
80-82	Average
83-85	High
Above 85	Very high

Fiber Elongation: Elongation is the degree of extension of the fibers before a break occurs when measuring strength and is expressed as a percentage. Fiber bundle elongation is correlated with yarn elongation but has an insignificant effect on yarn strength. Its value and importance in yarn manufacture has not been fully established.

**Fiber elongation
and descriptive designation**

4.9 and below	Very low
5.0-5.8	Low
5.9-6.7	Average
6.8-7.6	High
7.7 and above	Very high
